Abstract - A highly diastereoisoface-selective intramolecular hetero Diels-Alder reaction of homochiral camphor-derived thiabutadienes to afford novel, optically active bornene ring-fused dihydrothiopyrans is described for the first time.

Thiocarbonyl compounds have recently received considerable attention as synthetic tools with specific properties. In fact, such useful sulfur compounds have been proved as key intermediates with rich, specific reactivity in the synthesis of complex molecules and natural products. On the other hand, there are numerous examples of camphor derivatives that have been exploited, particularly as chiral sources. The attractive advantages of employing camphor in asymmetric synthesis are its relatively inexpensive and easy availability, potent transformation ability, and promising asymmetric induction due to the topological differentiation efficiency apparently by virtue of the rigid framework of its derivatives. Salama et al. recently reported the photolysis of thiocamphor for the synthesis of the 3,6-dihydro-1,2-dithiin system. Corre et al. have recently demonstrated that thiocamphor derivatives can also be utilized as useful synths for chiral ligands. Some recent reports also describe the synthesis of homochiral camphor-annulated (fused) heterocycles such as pyridines, pyroles, pyrazoles, and oxazolines, particularly for the use of chiral ligands. To the best of our knowledge, however, there have been no reports so far of the synthesis of bornene-fused homochiral dihydrothiopyrans. In the course of our investigation on \( \alpha,\beta \)-unsaturated thiocarbonyl compounds, we have reported asymmetric hetero Diels-Alder (HDA) reactions of thiabutadienes to afford optically active dihydrothiopyrans. We considered it worthwhile to incorporate the camphor framework into a heterodiene system for preparing a new chiral thiabutadiene. Furthermore, to the best of our knowledge, there have been no reports on the intramolecular, asymmetric thiabutadiene-Diels-Alder reaction. Here, we wish to report for the first time the synthesis of optically active, bornene-fused dihydrothiopyrans that involves a highly diastereoisoface-selective intramolecular HDA cycloaddition of 3-(arylmethylene)thiocamphors bearing a dienophile (2).
3-(Arylmethylene)camphors (1) were readily prepared by aldol condensation of natural (+)-camphor (4) with salicyl aldehyde (5), followed by introduction of a dienophile moiety with 7 to 6 (Scheme 1). When the ketones (1) were thionated with Lawesson's reagent (LR) in refluxing toluene or xylene for 1.5-3 h, the formed thioketones (2) smoothly underwent the intramolecular [4+2] cycloaddition to afford the cycloadducts (3) in good yields (Table 1). The formation of the thioketones (2) is apparent because

a Reaction was carried out by heating a mixture of ketone (1) (1.00 mmol) and Lawesson’s reagent (0.64 mmol) in a solvent (20 cm³). b Isolated yield. c Determined by ¹H NMR spectroscopy and HPLC analysis.
In the cases of 1b and 1f (R₁ = R₂ = Me), the characteristic blue color of the thioketones appeared, and relatively high temperature (ca. 140 °C) was required to complete the cycloaddition. In the other cases, such color was virtually not observed during the reaction. These facts suggest that the cycloaddition is slow enough in the former cases and is quite rapid in the latter, and that the rate-determining step is the cycloaddition process for the former cases and the thionation stage for the latter. The rate enhancement for the cycloaddition due to the intramolecularity is significantly large as the generated thioketones (2) (except for 2b, 2f) are so quickly trapped by the even less activated, inner dienophile (X = CH₂, R₁ = R₂ = H) when the thionation was performed in refluxing benzene or toluene for 1 h. In contrast, the intermolecular (bimolecular) cycloaddition of structurally analogous 3-(o-methoxyphenylmethylene)camphorthione, which could be isolated as a monomer, with an even activated dienophile such as methyl acrylate requires 6 h in refluxing benzene for completion of the cycloaddition.

The data in Table 1 suggest that the endo-exo stereoselectivity is affected by two variants, viz., the tether connector X (CH₂ / CO) and the substituents (R₁ / R₂): Namely, in the cases of X = CO group, the cis (endo) isomers are formed with high selectivity except for the case of e (R₁ = R₂ = H), whereas the cis-trans (endo-exo) selectivity is largely varied in the cases of X = CH₂ group. In the latter cases (X = CH₂), formation of the exo (trans) isomers is preferred when the substituents R₁ and R₂ are the same (H or Me, Entries a and b), whilst the cycloaddition with the dienophile having a substituent R₁ only (R₁ = Me or Ph, R₂ = H) trans to the chain shows the endo preference (Entries c and d). This stereochemical outcome can be explained by considering the transition states as illustrated in Figure 1. When X is a CH₂ group, the stereochemical outcome is due mainly to the steric repulsion, depending on the substituents R₁ and R₂, around the diene and the dienophile. When X is a CO group (Entries f-i), the secondary orbital interaction between the CO carbon and diene C-3 carbon orbitals strongly controls the endo (cis)-selectivity of the cycloaddition compared to that of the intermolecular variant. This can be ascribed to the effective arrangement involving the enhanced secondary orbital interaction of the carbonyl group which is connected by the tethering aryloxy group with less steric repulsion by arranging nearly perpendicular to the diene plain, where the acrylic dienophile consequently adopts s-cis conformation with respect to the C=C-CO moiety in the endo transition state. With regard to the diastereo-π-facial differentiation, the dimethyl substituents at the 7-position of the bornene skeleton block the dienophile
attack from the upper side in either (exo/endo) transition state, thus showing good to excellent diastereomeric excess (de).

The diastereoisomers of the cycloadducts (3) were spectroscopically (1H-NMR) discriminated, and chromatography and fractional recrystallization could separate them except for 3a, 3b and 3d. Being obtained as oils, compounds (3a, b, d) were oxidized by mCPBA to afford sulfoxides (8a, b, d), the major isomers of which were separated. The stereochemistry of the cycloadducts (3) was determined on the basis of 1H-NMR spectroscopy and the comparison with that of cis-3e (major), of which the absolute configuration was unequivocally confirmed by X-Ray crystallographic analysis.18

In summary, we have demonstrated that a highly diastereoisoface-selective intramolecular hetero Diels-Alder cycloaddition of homochiral camphor-derived thiabutadienes is a viable approach to the synthesis of optically pure bornene ring-fused dihydrothiopyrans.

Further work is in progress along this line by applying the camphor-derived sulfides as chiral catalysts.

REFERENCES AND NOTES

14. **General procedure:** A mixture of 3-(arylmethylene)camphor (1) (1.0 mmol) and Lawesson's reagent (0.64 mmol as a dimer) in dry toluene or xylene (20 mL) was heated at reflux for 1-3 h under an argon atmosphere until the ketone (1) was consumed (monitored by TLC). After being cooled, the reaction mixture was filtered through a short column of a celite or silica gel pad. The filtrate was evaporated and the residue (1H-NMR analysis) was purified by chromatography on silica gel (AcOEt-hexane as an eluant) and recrystallization (AcOEt-hexane). **3e-cis (endo major):** mp 137.2-138.4 °C; IR (KBr) 1768 cm⁻¹ (lactone); [α]D +250.0 ° (CHCl₃, c 0.99, 28
