Abstract—The first synthesis and electrochemical characterization of 7,7′-diethyl-4,4′-ethylenedioxybis(benzo[1,2-d][1,2,3]trithiole) (A) containing two benzotri-thiole rings linked by an ethylenedioxy group are described.

Cyclic benzopolychalcogenides such as benzopentathiepins,1 benzotetrahiins,2 and benzothioliols3 have been studied by many heteroatom chemists in fields of synthetic, structural, and biological chemistry.4 We also established a synthetic methodology for obtaining benzopentathiepins5 and benzothioliols6 by the sulfurization-cyclization of the corresponding benzenedithiols or their synthetic equivalents. These successes in the synthesis of cyclic benzopolychalcogenides and related compounds have allowed us to study the interaction between the polysulfide ring and a functional group, such as amino and sulfide groups. We found out that the benzopentathiepin was stable toward cyclic amines such as pyridine and pyrimidine and sulfide moiety contained in the thiophene ring.7 Now our interests focused on the intramolecular interaction of two polysulfide rings linked with a spacer such as alkanediy1 and alkanedioxy groups. Here, we wish to report our preliminary findings on the first synthesis and electrochemical characterization of 7,7′-diethyl-4,4′-ethylenedioxybis(benzo[1,2-d][1,2,3]trithiole) (A), containing two benzothioliol rings linked by an ethylenedioxy group.

A route for the synthesis of bisbenzothioliol (A) was examined as follows (Scheme 1). Thus, tetrabromination of bis[1,2-(4-ethylphenoxy)]ethane (1) with bromine in CCl4 and then debromination of resulting 2 using n-BuLi afforded bis[1,2-(3-bromo-4-ethylphenoxy)]ethane (3) in high yield. A Grignard reagent obtained from 3 by reaction with magnesium in THF was treated with elemental sulfur and then reduced with NaBH4 under reflux of THF to give 1,2-bis(4-ethyl-3-mercaptophtenoxy)-ethane...
The dithiol (4) obtained was converted to 1,2-bis(4-ethyl-2,3-dimercaptophenoxy)ethane (5) by ortholithiation, sulfurization, and then reduction with NaBH₄. The treatment of 5 with thionyl chloride afforded trithiole-2-oxide (6) and reduction of 6 with sodium iodide in the presence of HClO₄ gave the desired bisbenzotrithiole, 7,7'-diethyl-4,4'-ethylenedioxybis(benzo[1,2-d][1,2,3]trithiole) (A) in 32% overall yield.

Next, we investigated the electrochemical property for A by cyclic voltammetry, which gave a clear reversible redox voltammogram based on one step oxidation-reduction as shown in Figure 2. The E₁/₂ (V) value of 0.62 V obtained for A is close to the one for 1-ethyl-4-methoxybenzotrithiole (Table 2). This result suggests that a radical cation species could be formed electrochemically by the oxidation of A and could return to a neutral molecule by reduction. Moreover, it was found that each ring of the two

The structure of bisbenzotrithiole (A) was confirmed spectroscopically and finally determined by X-Ray crystallography. The ORTEP drawing of compound (A) was shown in Figure 1. According to the result of X-Ray crystallography (Table 1), most bond lengths and angles and torsion angles of each trithiole ring were similar to the previous data for the benzotrithiole ring. It is very interesting that the structure of A is linear and the two benzotrithiole rings are independent of each other. We were not able to observe any interaction between the two benzotrithiole rings in the crystal packing (Figure 1).
trithioles was oxidized independently. Based on the results of electrochemistry, the oxidation of bisbenzotri thiolo (A) was investigated using two equivalents of one electron oxidant. Thus, the oxidation of A with NOPF$_6$ in a mixed solvent of CH$_2$Cl$_2$/MeCN gave a dark blue powder product, bis-radical cation (A$^{2+}$)$_2$,¹³ which decomposed at 109.2 ºC (Scheme 2).

\]

A typical septet peak at -143.7 ppm ($^3$JP-F = 707 Hz) of the $^{31}$P NMR spectrum based on the formation of a bis-radical cation (A$^{2+}$) appeared as shown in Figure 3 and the structure was finally established by elemental analysis. Using ESR spectroscopy, we were able to measure the bis-radical cation (A$^{2+}$) to show a broad signal at g = 2.017 G as shown in Figure 4,¹⁴ but the super fine structure could not be detected. These results suggest that both benzotri thiole rings were oxidized simultaneously by one electron oxidant, NOPF$_6$, to form two radical cations in the molecule.
