A SIMPLE PREPARATIVE METHOD OF N-ARYLINDIGOS AND SUBSTITUTION EFFECT IN UV/VISIBLE ABSORPTION

Yukihiro Matsumoto and Hitoshi Tanaka*

Department of Optical Science and Technology, Faculty of Engineering, Tokushima University, 2-1 Minamijosanjima, Tokushima 770-8506, Japan

Abstract- N-Aryl- and N', N'-diarylindigos were prepared by refluxing corresponding aryl iodides or bromide with indigo in o-dichlorobenzene. Variation of their UV/visible spectra with the ring-substitution was discussed on the basis of the captodative and steric effects.

Organic pigments have recently been looked over again as new functional materials including optical components. Among them, indigos including N, N'-dialkylindigos and N, N'-diacylindigos exhibit characteristic behaviors in matrices or under light irradiation. A large bathochromic shift of the longest-wavelength absorption maximum, for instance, was observed in the UV/visible spectrum when NH hydrogens in indigo were replaced by alkyl groups, which was first recognized to be the inductive effect of the alkyl groups. After that, however, such a bathochromism was considered to be due less to the inductive effect than to the steric interaction (Brunnings-Corvin effect) with the carbonyl group, i.e. twisting of the central C-C double bond. Studies on the UV/visible spectral change of indigos are thereby now focused on the existence and quantification of an inductive or mesomery effect (captodative effect) as well as a steric effect. Fijter and coworkers examined an extent of the mesomery effect using various vinylogous N, N'-dialkylindigos with stereochemically identical and planar structure. Unfortunately, however, a configuration of vinylogous N, N'-dialkylindigos prepared varied with the alkyl substituents, i.e. the cis/ trans and nonplanar/planar structures, which makes it difficult to quantify the effects.

In addition, in our continuous work on the captodative (cd) effect, the electronic push and pull powers of each cd substituent and the synergistic cd power have often been discussed to elucidate a cd stabilization effect in reaction. Estimation of such an electronic power has been attempted theoretically and empirically on the basis of the ESR spectral data, but it is rather impractical. Recently, we could prepare N-mono- and N, N'-diarylindigos through one step reaction by improving the Ullmann-Goldberg reaction. N-Arylindigos are of particular interest in connection with the bathochromic and cd substituent study of N-subsituted indigos as well as a construction of new types of indigo π-system. In the present study, we deal with the synthesis and light absorption of the arylindigos (1~5) in an approach to quantify the electronic and steric effects.

Refluxing an iodobenzene with indigo in o-dichlorobenzene containing Cu powder and K₂CO₃ for 10 h gave reddish purple needles in 91.7% yield, which was assigned to N, N'-diphenylindigo (2a) by the NMR
and MS spectra. Products and their yield greatly depended on the reaction conditions, and the decrease in molar ratio of iodobenzene/indigo or reaction time resulted relatively in the increase of the amounts of \(N\)-phenylindigo (1a), and the decrease of \(N\), \(N\)'-disubstituted analogue (2a). Reduction of the reaction time to 5 h, for instance, produced mainly \(N\)-monophenyl substituted indigo (1a) in 53.5% yield, accompanied by

$a$) $\lambda_{\text{max}}$: nm  
$b$) Groups in the parentheses indicate a p-substituent on N-phenyl ring.

< OCH$_3$, which is compatible with an electron-donating power of the substituents, e.g., 0.66, 0.45, 0.06, 0.00, and -0.27 of the Hammett $\sigma_p$ substituent constants respectively. Such a bathochromic shift can be recognized to originate almost from an enhanced resonance stabilization, i.e., the captodative effect, since molar extinction coefficient ($\varepsilon$) of 1a–1d and 4 varied little ($\varepsilon$=15,300–16,900 in CHCl$_3$) and the difference in steric hindrance between them is negligibly small, i.e., their $p$-substituents are far apart each other from the central C-C double bond of the indigo skeleton. While, in cyanophenylindigos (1d) and (2d), $\lambda_{\text{max}}$ is longer in di-substituted 2d than mono-substituted 1d in spite of the decreasing captodative effect of 2d, suggesting a bathochromic shift due to the steric hinderance. It is concluded thereby that the bathochromism observed in the N-substituted indigos originates not only from the Brunnings-Corvin effect but also from the captodative effect.

EXPERIMENTAL

Measurements

Melting points were determined on a Japan Hightech THM 600 hot-stage apparatus with a cooling system. $^1$H-NMR spectra were measured in CDCl$_3$ at 23 $^\circ$C on a JEOL JNM-EX400 (400 MHz) spectrometer using tetramethylsilane as an internal standard. UV/visible spectra were recorded on a Shimazu UV-1600PC using 1cm light-path length quartz cell. MS spectra were taken with Shimazu QP 1000 spectrometer. Analytical TLC was performed on Merck silica gel RP-18F$_{254}$S plates. Column chromatography was carried out on Cica silica gel 60, 0.063–0.210 mm.

Materials

General procedure for the synthesis of compounds (1) and (2)

1 and 2 were generally prepared by refluxing $o$-dichlorobenzene solution containing commercially available indigo, iodobenzene, copper powder, and potassium carbonate in a round bottom flask equipped with a condenser for given time. The reaction was traced by TLC analysis. After the reaction dilute HCl (1 N) was poured into the reaction mixture, following the filtration and washing with chloroform. Solvents including $o$-dichlorobenzene and chloroform were removed from the residue under reduced pressure. Then,
the products were isolated by a column chromatography using chloroform for compounds a ~ c and chloroform/acetonitrile (20/1) for d as developing solvents.

**N-Phenyl- and N, N'-diphenylindigos (1a) and (2a)**

The mixture of indigo 1.05 g (4.0 mmol), iodobenzene 0.92 mL (8.4 mmol), copper powder 0.027 g (0.42 mmol), and potassium carbonate 1.17 g (8.4 mmol) was refluxed in o-dichlorobenzene (20 mL) in a round bottom flask equipped with a condenser for 5 h. Isolation by a column chromatography gave 0.722 g (53.5%) of 1a and 0.515 g (31.1%) of 2a. Longer reaction time (10 h) afforded preferentially 2a in 91.7% yield. Recrystallization from chloroform and dichloromethane gave deep blue needles (1a) and reddish purple needles (2a); mp 265 and 326°C (decomp) respectively. 

1H-NMR of 1a: δ 6.88 (1H, t, J=7.6 Hz), 6.94 (1H, d, J=8.3 Hz), 6.99 (1H, d, J=8.1 Hz), 7.07 ppm (1H, t, J=7.3 Hz), 7.36~7.54 (8H, m), 7.82 (1H, d, J=7.6 Hz), 10.57 ppm (1H, s); MS (70 eV): m/z (%) 338 (M+, 100), 309 (30), 179 (14), 104 (11), 77 (24), 76 (22), 51 (16); Anal. Calcd for C_{22}H_{14}N_{2}O_{2}: C, 78.09; H, 4.17; N, 8.28. Found: C, 78.17; H, 4.41; N, 8.22.

1H-NMR of 2a: δ 6.59~7.87 (18H, m); MS (70 eV): m/z (%) 414 (M+, 100), 397 (33), 385 (51), 369 (11), 267 (42), 207 (15), 195 (15), 152 (10), 102 (10), 77 (47), 51 (22); Anal. Calcd for C_{28}H_{18}N_{2}O_{2}: C, 81.14; H, 4.38; N, 6.76. Found: C, 80.88; H, 4.62; N, 6.68.

**N-naphthylindigo (3)**

Preparation of 3 was similar to that of 1 and 2, in which 1-naphthyliodide was used instead of iodobenzene. In the reaction in naphthyliodide/indigo=2.1 molar ratio for 13 h reaction, 3 was obtained in 60.0% yield. Recrystallization from acetonitrile gave reddish purple plates; mp 258°C (decomp). 

1H-NMR of 3: δ 6.50 (1H, d, J=8.1 Hz), 6.79 (1H, t, 8H, J=7.3 Hz), 6.96 (1H, d, J=8.1 Hz), 7.06 (1H, t, J=7.3 Hz), 7.32~8.02 (11H, m), 10.69 ppm (1H, s); Anal. Calcd for C_{26}H_{16}N_{2}O_{2}: C, 80.40; H, 4.15; N, 7.21. Found: C, 80.64; H, 4.40; N, 7.11.

**N-p-Hexanoxycarbonylphenyl and N, N'-di(p-hexanoxycarbonylphenyl)indigos (4) and (5)**

p-Iodobenzoic acid hexyl ester was prepared by refluxing p-iodobenzoic acid 2 g (8 mmol) and 1-hexanol 15 mL (24 mmol) in the presence of a few drops of H_{2}SO_{4} for 1 h in a three-necked round bottom flask equipped with a Dean-Starks apparatus. Colourless oily ester was obtained in 70.3% yield after evaporating excess 1-hexanol. 4 was obtained by the reaction with p-iodobenzoic acid hexyl ester in a similar manner to that of 1 in 24.1% yield, accompanied by trace amount of 5, in which the molar ratio of the ester to indigo was 1.5 and the reaction time was 13 h. After reaction, 4 was isolated as bluish purple needles by a column chromatography using chloroform/dichloromethane (10/1) as developing solvents and following recrystallization from acetonitrile; mp 178°C (decomp). In the conditions in 3.0 molar ratio of the ester to indigo and the reaction time of 17 h, 5 was obtained selectively in 80.7% yield without a column chromatography. Recrystallization from acetone gave reddish purple needles (5); mp 153~154°C. 

1H-NMR of 4: δ 0.92 (3H, t, J=7.0 Hz), 1.35~1.82 (8H, m), 4.34 (2H, t, J=6.6 Hz), 6.91 (1H, t, J=7.6 Hz), 7.01 (1H, d, J=8.1 Hz), 7.02 (1H, d, J=8.3 Hz), 7.11 (1H, t, J=7.3 Hz), 7.43 (2H, d, J=8.4 Hz), 7.41~7.50 (3H, m), 7.84 (1H, d, J=7.6 Hz), 8.19 (2H, d, J=8.4 Hz), 10.49 ppm (1H, m); Anal. Calcd for C_{29}H_{26}N_{2}O_{4}: C, 74.66; H, 5.62; N, 6.00. Found: C, 74.40; H, 5.80; N, 5.86. 

1H-NMR of 5: δ 0.92 (6H, t, J=7.1 Hz),...
1.34–1.80 (16H, m), 4.34 (4H, t, $J=6.6$ Hz), 7.04 (2H, t, $J=7.5$ Hz), 7.10 (2H, d, $J=8.5$ Hz), 7.42 (1H, dd, $J=7.5, 8.3$ Hz), 7.59 (2H, d, $J=7.5$ Hz), 7.63 (4H, d, $J=8.5$ Hz), 8.23 ppm (4H, d, $J=8.5$ Hz); Anal. Calcd for C$_{29}$H$_{28}$N$_2$O$_4$: C, 75.20; H, 6.31; N, 4.18. Found: C, 75.00; H, 6.37; N, 4.05.

ACKNOWLEDGEMENT
The authors are greatful to Prof. Y. Miura of Osaka City University for the measurement of X-Ray diffraction.
