Abstract – Several new artificial analogs (3-6) of mycalamide A (1), a potent antiviral and antitumor agent, were synthesized through a coupling reaction of a bicyclic amine (19) with two tetrahydropyrancarboxylic acids (15) and (18), and their cytotoxicity and antiviral activity were tested.

INTRODUCTION

The mycalamides were isolated from a marine sponge of the *Mycale* genus found in New Zealand. Structurally related compounds, onnamides and theopederins, have also been isolated from a Japanese marine sponge of the genus *Theonella*. Interestingly, the structure of these compounds is strikingly similar to that of pederin, a strong insect poison isolated from *Paederus fuscipes*. The mycalamides exhibit potent in vitro cytotoxicity and in vivo antitumor activity as well as potent antiviral activity. In addition, mycalamide A (1) is reported to have immunosuppressive activity via inhibition of T-cell activation and to be 10-fold more potent than FK-506. As a result, the mycalamides have attracted much attention of synthetic organic chemists. The structure-activity relationship studies of simple derivatives...
prepared from naturally occurring mycalamides and their model compounds have been also reported. In preceding papers, we reported stereoselective total syntheses of mycalamide A (1). We also prepared its simplified analogs, and revealed their cytotoxicity and antiviral activity did not decrease by removing the C-3 methyl and/or C-4-exomethylene group on the left half segment of 1. Furthermore, analog (2) that replaced the right half by glucose derivative showed almost the same cytotoxicity against HeLa cells as that of 5-fluorouracil and good antiviral activity (MIC 3.125 µg/mL, IC50 >50 µg/mL) against VZV. These interesting results prompted us to investigate the effect of the methylene and/or methyl group in 2 on the inhibitory activities. Here, we describe synthesis of several new analogs (3-6).

RESULTS AND DISCUSSION

For the syntheses of 3-6, 3-desmethyl-4-desmethylenepederic acid (15) and 3-desmethylpederic acid (18) were needed. In previous work, syntheses of 15 and 18 required 13 (6% overall yield) and 20 steps (2% overall yield) from methyl (R)-3-hydroxybutyrate (7), respectively. In order to shorten the synthetic route, we developed a highly efficient synthesis of these compounds. Our new process involves Claisen condensation of a γ-lactone (8) with a methyl glycolate derivative (9) as a key step (Scheme 1). The usefulness of this procedure was demonstrated in our synthesis of methyl pederate. Generation of a lithium enolate of 9 at −78 °C followed by addition of ZnCl2 gave the corresponding zinc enolate, which reacted with 8 to afford a mixture of coupling products (10). Upon treatment with methyl orthoformate in the presence of CSA in methanol-CH2Cl2, 10 afforded a ca. 23:1 of diastereomeric mixture (11) in 76% yield. As described previously, both yield and stereoselectivity were reduced as a result of no ZnCl2 being added. After benzylation {BzCl, N,N-dimethylaminopyridine (DMAP), pyridine} of 11, the resulting compounds were separated into a (7S)-benzoate (12) (88%) and the corresponding (R)-isomer (13) (4%) by chromatography on silica gel. The newly created stereochemistry was confirmed by the transformation of 12 into the known compounds (15) and (18) (vide infra). The ethylenedithio moiety in 12 was removed by radical reaction using tributyltin hydride in the presence of 2,2′-azobisisobutyronitrile in toluene at 90 °C to give an ester (14) in 76% yield. This was subjected to demethylation with lithium propanethiolate in HMPA to give the corresponding carboxylic acid (15) quantitatively. On the other
hand, the thioacetal moiety in 12 was hydrolyzed by treatment with HgO-HgCl₂ in aqueous acetonitrile to afford a ketone (16) in 83% yield. Methylation of 16 was performed by Takai-Nozaki's method¹⁵ to afford an olefin (17) in 73% yield. Treatment of 17 as described for preparation of 15 from 14 gave the corresponding carboxylic acid (18) quantitatively. The overall yields of 15 and 18 from 7 attained 37% (7 steps) and 30% (8 steps), respectively.

Scheme 1. Reagents and conditions: a) ref. 12b, 76%; b) LDA, ZnCl₂, THF-Et₂O, −78~−40 °C; c) HC(OMe)₃, CSA, CH₂Cl₂-MeOH, rt, 76% from 8 in 2 steps; d) BzCl, DMAP, pyridine, 0 °C~rt, 88% for 12, 4% for 13; e) n-Bu₃SnH, AIBN, toluene, 90 °C, 76%; f) n-PrSLi, HMPA, rt, quant.; g) HgO, HgCl₂, MeCN, H₂O, rt, 83%; h) Zn, TiCl₄, CH₂I₂, THF, 0 °C~rt, 73%.

After obtaining the key intermediates, we turned our attention to the coupling reaction with a bicyclic amine (19) (Scheme 2).¹¹ Activation of the carboxylic acid (15) was performed by treatment with p-TsCl and DMAP in CH₂Cl₂ followed by addition of the amine (19) to afford a 10α-amide (20) and the corresponding 10β-isomer (21) in 14 and 46% yields, respectively. The newly created stereochemistry was determined by the coupling constant value of C-10 proton.⁸a Thus, the proton derived from C-10 of 20 was observed at 5.73 ppm as triplet with \( J = 8.5 \) Hz, while that of 21 at 5.38 ppm as a doublet of doublets (\( J_{10,11} = 2.0 \) Hz, \( J_{10,NH} = 9.8 \) Hz). Each compound was hydrolyzed by LiOH in H₂O-methanol to
provide the new analogs (3) and (4) in good yield. In a similar way, the carboxylic acid (18) was coupled with the amine (19) and the resulting amides (22 and 23) were transformed into the analogs (5 and 6), respectively.

Scheme 2. Reagents and conditions: a) p-TsCl, DMAP, CH₂Cl₂, 0 °C~rt, 16% for 20, 52% for 21, 6% for 22, 55% for 23; b) LiOH, MeOH-H₂O, 0 °C~rt, 86% for 3, 70% for 4, 65% for 5, 98% for 6.

The cytotoxicity and antiviral activity of the analogs (3-6) were tested according to a method previously reported. In a cytotoxicity test, compound (5) was found to have a weak antitumor activity against HeLa cell (IC₅₀ = 51.4 µg/mL), while no compound showed the antiviral activity against HSV-1 and VZV at less than 50 µg/mL. These results suggest that the presence of the C-3 methyl and/or C-4-exomethylene group on the left half segment of 2 is important for such biological activities.

In summary, we developed a new synthesis of the left half analogs of 1 and synthesized several new analogs (3-6) therefrom. The design and synthesis of the artificial analogs of 1 are under further investigation.

EXPERIMENTAL
Preparation of methyl acetal (11). To a stirred solution of LDA prepared from diisopropylamine (1.6 mL, 12.2 mmol) and n-BuLi (7.7 mL, 1.59 M in hexane, 11.8 mmol) in THF (25 mL) was added dropwise 9 (1.9 mL, 12.2 mmol) at −78 °C. After 0.5 h, a 1.0 M ether solution of ZnCl₂ (11.8 mL, 11.8 mmol) was added and the solution was stirred for 0.5 h. Then, a solution of 8 (804 mg, 3.94 mmol) in THF (5 mL) was added at −78 °C, and the mixture was stirred at −78 °C for 2 h and −78−−40 °C for 3 h. After quenching with addition of sat. NH₄Cl solution, the resulting mixture was extracted with ether. The extracts were washed with water, brine, dried over anhydrous MgSO₄, and concentrated. The residual
syrup was passed through a short column of silica gel \( \text{CHCl}_3 \rightarrow \text{CHCl}_3\text{-EtOAc (10:1)} \) to afford 10 (1.87 g), which was dissolved in \( \text{CH}_2\text{Cl}_2\text{-methanol (1:1, 50 mL)} \). To this solution were added methyl orthoformate (5.5 mL, 50.3 mmol) and CSA (377 mg, 1.62 mmol) at rt, and the mixture was stirred at rt for 4.5 h. After addition of sat. \text{NaHCO}_3 solution, the resulting mixture was extracted with \( \text{CH}_2\text{Cl}_2 \). The extracts were washed with water, brine, dried over anhydrous \( \text{MgSO}_4 \), and concentrated. Chromatography on silica gel with hexane-ether (3:1) as the eluent yielded 11 (929 mg, 76%) as a diastereomeric mixture (\( \text{7S} / \text{7R} = \text{ca. } 23/1 \) by \( ^1\text{H}-\text{NMR} \) spectrometry).

Preparation of 3-desmethyl-4-desmethylenemycalamide analog (3). To a stirred solution of 20 (9.9 mg, 15.2 µmol) in methanol (0.4 mL) was added a 1.0 M LiOH solution (0.2 mL) at 0 °C, and the mixture was stirred at 0 °C~rt for 2 h. After addition of brine, the resulting mixture was extracted with CH_2Cl_2. The extracts were dried over anhydrous MgSO_4 and concentrated. Chromatography on silica gel with CH_2Cl_2-MeOH (1:0 → 50:1) as the eluent yielded 3 (5.5 mg, 86%) as an amorphous solid.
