Abstract — Benzodioxane prostacyclin analogue ((±)-1) was synthesized via stereocontrolled construction of cyclopentanobenzodioxane (17) (7, R² = MOM) utilizing the Mitsunobu reaction, and subsequent introduction of the propenyl group into 17 by radical C-C coupling leading to 19 (8, R² = MOM).

Much effort has been devoted to the syntheses of stable prostacyclin analogues¹ to overcome the instability of natural prostacyclin (2) caused by the inherent labile enol ether-linkage and get better therapeutic efficacy.

In the course of these studies, it has been shown that, in spite of their noticeable structural deviations from natural 2, benzopyran- and benzindene prostaglandins (3²a and 4²) are strong prostacyclin-like inhibitors of platelet aggregation, and that 4 is cytoprotective as well. In these compounds, the central ring systems, together with the benzene ring, seemed to play an important role for the spatial arrangement required for the biological activities, and we were interested in modulating this part. In this paper, we report the synthesis of a new stable benzodioxane prostacyclin analogue ((±)-1).

The outline of our synthetic plan is shown in Scheme 1. The construction of the functionalized cis-fused cyclopentanobenzodioxane (7) and introduction of a carbon synthon to C₁₂ (PG numbering) of 7, both in a completely stereocontrolled manner, constitute the core of our synthesis.

We envisioned that the configuration in epoxy alcohol (6) carrying four contiguous stereogenic centers, could be securely transferred into 7 by a series of reactions, namely, condensation with differentially
protected pyrogallol (5) using the Mitsunobu reaction,\textsuperscript{3a} removal of the protecting group R\textsubscript{1} and dioxanering formation with concomitant epoxide-ring opening. For introduction of a carbon synthon to C\textsubscript{12}, we relied on an approach of trapping the radical derived from the thionocarbonate of alcohol (7) with allylttributyltin.\textsuperscript{4} Finally, further extension of α- and ω-side chains via α,β-unsaturated aldehyde (9) was expected to afford the desired benzodioxane prostacyclin analogue (\((\pm)-1\)) (Scheme 1). The feasibility of our plan was established as follows (Scheme 2).

1) Synthesis of the functionalized cis-fused cyclopentanobenzodioxane (17) (7, R\textsubscript{2} = MOM)
One of the components of 17, 1,3-di-O-protected pyrogallol (11), was obtained in 63% overall yield from 2,6-dimethoxyphenol (10) by a sequence of protection-deprotection procedures consisting of mesylation, selective monodemethylation with BBr\textsubscript{3}, protection with SEM group and demesylation with n-BuLi, while the other component, 2,3-epoxy alcohol (15), was prepared in 67% overall yield from the known allylic sulfide (12)\textsuperscript{5} in a stereochemically unambiguous way. Thus, the sulfoxide (13) obtained from 12 was subjected to sulfoxide-sulfenate rearrangements\textsuperscript{5} to give allylic alcohol (14), which was further oxidized to 15. The most crucial condensation of these two bulky components was effected by the Mitsunobu reaction\textsuperscript{3b} (11 1 eq., 15 1.2 eq., DEAD 1.5 eq., Ph\textsubscript{3}P 1.7 eq./THF, room temperature, 3 days, 87% from 11) to give seco-compound (16) with inversion. To our satisfaction, treatment of 16 with n-Bu\textsubscript{4}NF in THF at 55°C brought about not only removal of the SEM group, but also cyclization to the desired 17 (93%).

2) Introduction of the propenyl group to C\textsubscript{12} of cyclopentanobenzodioxane (17)
Thionocarbonate (18) prepared from alcohol (17) was irradiated with a high-pressure mercury lamp in the presence of allylttributyltin to obtain 12β-propenyl-substituted compound (19, 75%) as a single isomer, indicating that the approach of allyltin to the intermediary radical occurred exclusively from the less hindered convex side.

NaOH-MeOH-THF (70%).

Scheme 2
3) Extension of side chains
Starting from 19, the α-side chain was built up by demethylation and subsequent alkylation using methyl bromoacetate, which was followed by exchange of the MOM protecting group for TBDPS group to give 20 in 81% overall yield. Elaboration of the ω-side chain commenced with conversion of 20 into allylic chloride (21) (E/Z = 13/1, 77%) by consecutive treatment with phenylselenenyl chloride and hydrogen peroxide in one pot. In the next step, by reaction with cesium acetate, 21 was transformed into allylic acetate (22), which was then purified, by single recrystallization to obtain the pure E-isomer in 80% yield. Further conversion of E-22 to α,β-unsaturated aldehyde (23, 90%) was done by methanolysis and subsequent PCC oxidation. In the last stage of extension, treatment of aldehyde (23) with n-pentylimagnesium bromide (1.2 eq., -78°C) gave a mixture of alcohols, 15α-OH (247a, less polar, 48%) and 15β-OH (257b, more polar, 23%), together with recovered 23 (21%). Finally, stepwise deprotection by desilylation and hydrolysis completed the synthesis of benzodioxane prostacyclin analogue (±)-1a, along with its methyl ester (±)-1b.

Compound (±)-1a and its methyl ester (±)-1b showed very weak platelet aggregation inhibitory activity (IC_{50} = 1.35 μM and 4.58 μM, respectively, ADP, rabbit PRP), while the latter was cytoprotective against HCl-EtOH-induced ulcer in rats (ED_{50} = 52 μg/kg). Thus compound (±)-1b has turned out to be a new lead substance after which selective antiulcer prostacyclin analogues can be modeled. Further studies in modification of ω-side chains and structure-activity relationship will be reported in the future.

ACKNOWLEDGEMENT
We thank Drs. K. Uchida and M. Doteuchi for testing the biological activities.

REFERENCES AND NOTES
3. a) O. Mitsunobu, Synthesis, 1981, 1. b) To the best of our knowledge, no example of the intermolecular Mitsunobu reaction between 2,6-disubstituted phenol and alicyclic alcohol has been reported.

7. a) After removal of the 11-hydroxy-protecting group, 15α-OH 1b is more polar than the corresponding 15β-OH isomer in accordance with the generally accepted rule. b) The structure of 25 was established unambiguously on the basis of X-ray crystal analysis. Details will be reported in Acta Crystallogr. by Dr. M. Shiro of our laboratories.

8. All new compounds were characterized by 1H-nmr and ir spectra and gave satisfactory elemental analyses and mass spectra.
