Abstract - Furyl- and thienylacrylates (8-14) and acrylic acids  
(8a,10a-14a) are prepared in moderate yields by palladium catalysed  
coupling of substituted bromofurans and bromothiophenes with ethyl  
acrylate.

Our continuing interest in the synthesis and photochemistry of heterocyclic acrylic acids or substituted heterocyclic acrylic acids<sup>1-5</sup> has prompted us to develop a synthetic method for the preparation of new furyl- and thienylacrylates (8,9,10 and 12) substituted with carboxy substituent either in the position 4 or 5 of the heterocyclic nucleus or with *o*-chloroanilido substituent attached to the position 5 of the furan nucleus. Diethyl 5-carboxy-2,3-furandiacrylate (11), diethyl 5-carboxy-2,3-thiophenediacrylate (13) and diethyl 2,5-thiophenediacrylate (14) have also been prepared by palladium catalysed coupling of bromofurans and bromothiophenes with ethyl acrylate. Corresponding acids (8a,10a-14a) have been prepared from previously obtained esters.

Palladium catalysed coupling of bromo or iodo substituted aromatic compounds with vinyl substituted reagents (ethyl acrylate, acrylonitrile, styrene, vinyl methyl ketone) is a well known and usefull reaction for the preparation of vinyl substituted aromatic compounds.<sup>6-11</sup> There has been however, only one article reporting on the Heck reaction of heterocyclic carboxylic acids.<sup>12</sup>

The ordinary Wittig reaction used for preparing aromatic or heterocyclic compounds substituted by vinyl or substituted vinyl group does not always give the good yields in heterocyclic series. Besides, the products are always a mixture of cis- and trans-isomers. On the other hand the preparation of the o-disubstituted diacrylates requires a multistep synthesis.<sup>13</sup>

Palladium catalysed acrylation (vinylation) is a more convenient reaction and the yield ranges from 40-88%.<sup>6-12</sup>

The vinylation of all bromo compounds (1-7) was investigated under standard Heck conditions. These consisted of heating an acetonitrile solution of bromo compound with an excess of ethyl acrylate and triethylamine in the presence of 1% palladium(II) acetate and 2-6% of triphenylphosphine at 100°C for 12-20 hours. The results are summarized in Table 1. Moderate yields of yellow crystalline products (8-14 and 8a-14a) were obtained. The stereochemistry of the double bond in the acrylates (8,9,10,12) and in the diacrylate (14) was exclusively trans as shown by the  $J_H$  of 16 Hz from one or two olefinic doublets in the relevant <sup>1</sup>H nmr spectra. It is important to emphasize that the stereochemistry of the double bonds was exclusively trans. However, the vinylic hydrogen atoms A' and B' in the acrylate attached to the position 3 of the heterocyclic nucleus are shifted in relation with vinylic hydrogen atoms A and B.
