Abstract- The 1,3-dipolar cycloadditions of aceto-, benzo- and bromoformonitrile oxides to cyclic and open-chain 4-oxobut-2-enoic acid derivatives have been investigated. The addition to 5-methoxyfuran-2(5H)-one (I) gave regioselectively 3-substituted 6-exo-methoxy-3a,6a-dihydrofuro[3,4-d]isoxazol-4(6H)-ones, whereas methyl (Z)- and (E)-4,4-dimethoxybut-2-enoates (2) and (3) afforded mixtures of regioisomeric isoxazolines.

INTRODUCTION

The 1,3-dipolar cycloaddition is one of the most useful methods for the construction of five membered heterocyclic rings. The cycloaddition reactions to 4-oxobut-2-enoic acid derivatives, including those of its ring-tautomer, afford functionalized heterocycles which are valuable intermediates for the synthesis of fused heterocyclic ring systems and other physiologically interesting molecules. However, there are few reports dealing with the use of these compounds as dipolarophiles, the only examples being the cycloaddition of diazomethane to 5-methoxyfuran-2(5H)-ones and to methyl (Z)- or (E)-4,4-dimethoxybut-2-enoates, described by us, the addition of aryl azides to 5-alkoxyfuranes, and the reactions of aryl nitrile oxides and diphenyltrinitrile with 5-hydroxy- or 5-alkoxyfuran-2(5H)-ones, reported by Fisera and Feringa. In the present paper we extend our study to the behaviour of 5-methoxyfuran-2(5H)-one (I), butenoates (2, 3) and their 2- and 3-bromo derivatives, towards benzo-, bromofumo-, and acetonitrile oxides. The reactions have been explored with cyclic and open-chain dipolarophiles to acquire information on the influence of the alkene structure upon reactivity and regioselectivity. Isoxazoles and isoxazolines, which are readily converted into polyfunctionalized derivatives, have received much attention as an important class of synthetic intermediates. The isoxazolines obtained by cycloaddition of nitrile oxides to 4-oxobut-2-enoic acid derivatives (1, 2 and 3) are appropriately functionalized and may serve as versatile synthetic intermediates for the construction of new fused heterocyclic ring systems.
RESULTS AND DISCUSSION

Benzonitrile oxide (BNO) (4) and bromoformonitrile oxide (5) were prepared by dehydrohalogenation of the corresponding hydroximic acid halides. All the cycloaddition reactions were run with excess of 1,3-dipole at room temperature under comparable conditions. The acetonitrile oxide (6) was generated "in situ" from nitromethane by the Mukaiyama’s method, and the cycloaddition reactions were carried out at room temperature and/or at 40 °C. The reactions were prolonged until disappearance of the dipolarophile was completed, the crude reaction mixtures being analyzed by $^1$H nmr. The furoisoxazolines were isolated by column chromatography.

Cycloadditions to 5-methoxyfuran-2(5H)-ones

Nitrile oxides (4-6) reacted readily with furanone (1) to afford the expected adducts in moderate yields. Only one regioisomer was produced in accord with the behaviour of other furan-2(5H)-ones and $\alpha,\beta$-unsaturated lactones towards this type of dipole. On the basis of the reported observations we have assigned the structure of type A (7-9) to the isolated furoisoxazoline derivatives, rather than the regiochemistry of type B (Scheme 1). The $^1$H nmr spectra of the adducts were also consistent with the assigned structure A.

![Scheme 1](attachment:image)

The trans relationship of H-6 and H-6a, and consequently the face-selectivity of the cycloadditions, was established by $^1$H nmr (Table I). In all the isolated furoisoxazolines (7-9), the acetal-type proton appears as a singlet. This fact suggests that the attack of dipole occurs preferently at the face opposite to the OMe group, although this is not a very bulky group. This observation is in accord with the face-selectivity reported

previously for the Diels-Alder reactions of furanone (1)\textsuperscript{11} and other 5-substituted butenolides,\textsuperscript{12} and for the 1,3-
dipolar cycloaddition of nitrones to the same type of dipolarophiles.\textsuperscript{13} It is interesting to note, however, that
the addition of diazomethane to 1 leads to a mixture of \textit{endo} and \textit{exo} adducts.\textsuperscript{3}

The proposed regiochemical assignment was further confirmed by conversion of 9 into 15b (Scheme 2),\textsuperscript{14} the
structure of which was assigned as shown below.

![Scheme 2](image)

It is remarkable that 3- or 4-bromo-5-methoxyfuran-2(5H)-ones\textsuperscript{15} do not react with the nitrile oxides (4, 5 and
6) under the experimental conditions employed for the furanone (1).

**Cycloadditions to methyl 4,4-dimethoxybut-2-enoates**

According to literature, cycloadditions of nitrile oxides with activated 1,2-disubstituted ethylenes, such as
crotonic and cinnamic esters, generally produce mixtures of regioisomers.\textsuperscript{16} Unfortunately, the behaviour of
methyl 4,4-dimethoxybut-2-enoates is not different in this regard. In fact, 1,3-dipolar cycloaddition of nitrile
oxides (4, 5 and 6) to the Z-butenoate (2) proceeded smoothly affording two regioisomeric adducts, each
appearing as a mixture of \textit{cis-} and \textit{trans}-4,5-disubstituted isoxazolines. Exception was found with acetonitrile
oxide (6) that afforded both regioisomers, although a single stereoisomer was produced in each case. The ratios
of regio- and stereoisomers obtained are summarized in Table II.

</table>
The structure of the regioisomeric isoxazolines was established on the basis of the chemical shift of the proton coupled with the acetal proton (Table III). In 5-methoxycarbonylisoxazolines (10, 12, and 14) H-4 appears as a double doublet at higher field than in the corresponding 4-methoxycarbonylisoxazolines (11, 13, and 15). The cis or trans relationship between protons H-4 and H-5 can directly be deduced from the magnitude of the coupling constant \( J_{4,5} \); in fact, smaller values were observed (compounds 10b-15b) when these protons are trans to each other, while larger values were present in the cis isomers (10a-14a).

If we admit a concerted mechanism, the formation of isoxazolines (10b-15b) with the methoxycarbonyl and dimethoxymethyl groups in a trans arrangement, which was not present in the starting dipolarophile (2), may be ascribed to a subsequent isomerization of the primary adduct. A similar isomerization has been observed in related cycloadducts.\(^{16b}\)

The 1,3-dipolar cycloaddition of nitrile oxides (4, 5, 6) to the \( E \)-dipolarophile (3) was carried out under experimental conditions similar to those used for the \( Z \)-ester, affording two regioisomeric adducts with complete retention of stereochemistry (Scheme 4).

The low regioselectivity observed in the cycloadditions of nitrile oxides (4, 5 and 6) to the open-chain dipolarophiles (2) and (3) (Table II) is in accord with the general fact reported for the additions of nitrile oxides to other 1,2-unsymmetrically substituted alkenes.\(^{2,17-19}\) The reactions of benzonitrile oxide (4) with \( Z \)- and \( E \)-butenoates (2) and (3) afford the 4-methoxycarbonylisoxazolines (11a,b) as the major regioisomers (\( A/B < 1 \), Table II) in agreement with the regiochemistry reported for the additions to crotonic and cinnamic esters.\(^{16} \) In contrast, the addition of acetonitrile oxide (6) to 2 and 3 gives the 5-methoxycarbonylisoxazoline (14) as the major regioisomer (\( A/B > 1 \)); this fact does not agree with the regiochemistry previously reported\(^{16a,c,d} \) for cycloadditions of dipole (6) to crotonic and cinnamic esters. It is noteworthy that the regioselectivity is significantly affected by the stereochemistry of the dipolarophile (\( A/B = 0.35 \) and 0.85 for \( Z \) and \( E \) dipolarophile, respectively), whereas the regioselectivity of acetonitrile oxide additions is barely influenced by the \( Z \) or \( E \) geometry of the dipolarophile. The results obtained for the cycloadditions of bromoformonitrile oxide (5) to the butenoates (2) and (3) parallel those obtained with the acetonitrile oxide (6).
As indicated above for the cyclic dipolarophile (1), a bromine atom linked to the double bond of the esters (2) or (3) practically inhibits the cycloaddition of the nitrile oxides (4-6) under the experimental conditions employed.

In summary, cycloadditions to the cyclic dipolarophile (1) occur with high face- and regioselectivity and proceed faster than those to the open-chain dipolarophiles (2 and 3).

**EXPERIMENTAL**

Mps are uncorrected. Ir spectra were recorded on a Phillips model P.V-9716 spectrophotometer ($\nu_{\text{max}}$, cm$^{-1}$). $^1$H and $^{13}$C nmr spectra were obtained on a Bruker WP 200SY spectrometer for CDCl$_3$ solutions, using TMS ($\delta$=0 ppm) as internal reference. Mass spectra were determined on a Hewlett-Packard model 5985. Silica gel Merck 230-400 mesh and DC-Alufolien 60 were used for flash and analytical thin layer chromatography, respectively.

The dipolarophiles (1), $^{20}$ (2), $^{21d}$ (3)$^{21d}$ and their halo derivatives$^{15a,b}$ were prepared according to the previously reported procedures.

**6-exo-Methoxy-3-phenyl-3a,6a-dihydrofuro[3,4-d]isoxazol-4(6H)-one (7)$^6$**

To a stirred mixture of 10% sodium hydroxide solution (20 ml) and ether (20 ml) was added portionwise during 10 min at 0 °C the benzaldehyde chloroxime (1.55 g, 10 mmol). The ethereal layer was separated, quickly dried over magnesium sulfate and added to a solution of the 5-methoxyfuran-2(5H)-one (1) (1.03 g, 9 mmol) in dry ether (10 ml). After stirring for 12 h at room temperature, a second addition of dipole (10 mmol) was made and the mixture allowed to stand at room temperature for 24 h. The adduct was isolated by filtration, mp 108-110 °C. Lit. $^6$ 109-111 °C. A second crop of 7 was obtained from the ethereal solution. Yield 60% (1.26 g). Ir (nujol): 1805, 1780, 1565. $^{13}$C Nmr: 169.6 (C-4), 152.4 (C-3), 130.7 (Ar), 128.6 (Ar), 127.7 (Ar), 126.5 (Ar), 107.7 (C-6), 86.7 (C-6a), 57.2 (C-3a), 53.7 (OMe). Ms, m/z (%): 233 (49), 174 (10), 144 (100), 115 (28), 104 (40), 77 (60).

**3-Bromo-6-exo-methoxy-3a,6a-dihydrofuro[3,4-d]isoxazol-4(6H)-one (8)**

To a vigorously stirred mixture of 5-methoxyfuran-2(5H)-one (1)(513 mg, 4.5 mmol), ethyl acetate (23 ml), sodium bicarbonate (773 mg, 9.2 mmol), and water (1.5 ml), was added solid dibromoformaldoxime (913 mg, 4.5 mmol) in small portions. Stirring was maintained during 30 h at room temperature. The precipitated salt was filtered off, the filtrate was dried (MgSO$_4$) and the solvent removed under reduced pressure. The residue analyzed by $^1$H nmr, contained the adduct (8) as the main component and traces of methyl 3-bromo-5-formylisoxazole-4-carboxylate. The crude product was chromatographed on silica gel (ethyl acetate-hexane 1:3) to afford the pure furoisoxazoline (8) in 45 % yield (478 mg). Recrystallized from carbon tetrachloride mp
105-108 °C. Anal. Calcd for C₈H₇NO₄Br: C, 30.51; H, 2.54; N, 5.93; Br, 33.90. Found: C, 30.60; H, 2.64; N, 5.91, Br, 33.98. Ir (nujol): 1810, 1780, 1565. ¹³C Nmr: 167.3 (C-4), 132.7 (C-3), 108.2 (C-6), 86.8 (C-6a), 58.1 (C-3a), 57.6 (OMe). Ms, m/z(%): 237-235 (2), 206-204 (4), 149-147 (53), 112 (53), 84 (100).

6-exo-Methoxy-3-methyl-3a,6a-dihydrufuro[3,4-d]isoxazol-4(6H)-one (9)
To a solution of 5-methoxy-2(5H)-furanone (1) (2.85 g, 25 mmol) and triethylamine (1 ml) in toluene (70 ml) was added phenyl isocyanate (5.95 g, 50 mmol), and nitroethane (2.24 g, 30 mmol) in four portions over a period of 1 h. Stirring was maintained during 4 h at room temperature. The precipitated N,N-diphenylurea was filtered off. Evaporation of solvent gave a residue, that was purified by column chromatography (ethyl acetate-hexane 1:3). Yield 70 % (2.99 g). Recrystallized from cyclohexane mp 70-73 °C. Anal. Calcd for C₁₆H₁₃NO: C, 49.12; H, 5.26; N, 8.19. Found: C,49.23; H, 5.45; N, 8.24. Ir (nujol): 1800, 1780. ¹³C Nmr: 169.7 (C-4), 150.7 (C-3), 108.9 (C-6), 85.2 (C-6a), 57.3 (C-3a), 57.2 (OMe), 10.9 (Me). Ms, m/z(%): 171 (3), 140 (3), 93 (76), 83 (56), 69 (100).

Cycloaddition of Benzonitrile Oxide (4) to Methyl 4,4-Dimethoxybut-2-enoates

a) To an ice cooled solution of methyl (Z)-4,4-dimethoxybut-2-enoate (2) (800 mg, 5 mmol) in methylene chloride (25 ml) was added with stirring triethylamine (2.1 ml, 15 mmol). To the stirred solution was added benzaldehyde chloroxime (800 mg, 5.5 mmol) in small portions. After 3 days at room temperature, a new portion of benzaldehyde chloroxime (5.5 mmol) was added and the mixture allowed to stand for 6 days. The solvent was removed under reduced pressure, after addition of hexane, the precipitate was filtered off and the solution washed several times with water. The organic layer was dried (MgSO₄), and after removing of solvent afforded a brown oil, that analyzed by ¹H nmr contains the isomeric isoxazolines (10a, 10b, 11a and 11b) in a 16:10:60:14 ratio. The products were separated by column chromatography (hexane-ethyl acetate, 3:1). Total yield 48% (670 mg).

b) Following the procedure outlined above, the E butenoate (3) and benzaldehyde chloroxime at room temperature (2 days after the first addition and 4 days after the second addition), gave a mixture which contained the regioisomeric isoxazolines (10b and 11b) in 46:54 ratio, determined by ¹H nmr. The products were separated by column chromatography (hexane-ethyl acetate, 3:1). Total yield 55% (767 mg).

Ir (film): 1750, 1610, 1580. ¹³C Nmr: 167.3 (C=O), 134.3 (C-3), 103.0 (C₆H₅), 84.8 (C-5), 58.4 (C-4), 56.8 (OMe), 55.4 (OMe), 53.2 (OMe).
Cycloaddition of Acetonitrile Oxide (6) to Methyl 4,4-Dimethoxybut-2-enoates

To a solution of methyl (Z)-4,4-dimethoxybut-2-enoate (2) (1.28 g, 8 mmol), triethylamine (0.4 ml), and phenyl isocyanate (2.14 g, 20 mmol) in toluene (36 ml), was added nitroethane (950 mg, 12 mmol) in four portions over a period of 4 h. Stirring was maintained during 24 h at 40 °C. The precipitated N,N-diphenylurea was filtered off. Evaporation of solvent gave a residue, whose \(^1\)H nmr analysis showed the presence of 14a and 14b in a 65:35 ratio. The products were separated by column chromatography (hexane-ethyl acetate, 3:1). Total yield 50% (868 mg).

b) Following the procedure outlined above, the E butenoate (3) after 18 h gave a mixture which contained the regioisomeric isoxazolines (14b and 15b) in a 60:40 ratio, determinated by \(^1\)H nmr. The products were separated by column chromatography (hexane-ethyl acetate, 3:1). Total yield 55% (955 mg).

Methyl cis-4-dimethoxymethyl-4,5-dihydroisoxazole-5-carboxylate (14a)

Anal. Calcd for C\(_9\)H\(_{12}\)NO\(_3\): C, 49.76; H, 6.91; N, 6.45. Found: C, 49.84; H, 7.10; N, 6.38. Ir (film): 1750, 1630, 1600. \(^{13}\)C Nmr: 169.1 (C=O), 155.3 (C-3), 101.4 (C\(_\alpha\)H), 78.6 (C-5), 55.9 (C-4), 54.4 (OMe), 53.9 (OMe), 51.9 (OMe), 12.6 (Me). Ms, m/z(%): 186 (4), 101 (3), 75 (100).

Methyl trans-5-dimethoxymethyl-4,5-dihydroisoxazole-4-carboxylate (15b)

Anal. Calcd for C\(_9\)H\(_{12}\)NO\(_3\): C, 49.76; H, 6.91; N, 6.45. Found: C, 50.10; H, 7.20; N, 6.30. Ir (film): 1740, 1630, 1600. \(^{13}\)C Nmr: 168.3 (C=O), 151.9 (C-3), 103.2 (C\(_\alpha\)H), 82.6 (C-5), 56.5 (C-4), 55.8 (OMe), 54.8 (OMe), 52.4 (OMe), 11.7 (Me).

Methyl trans-4-dimethoxymethyl-4,5-dihydroisoxazole-5-carboxylate (14b)

Anal. Calcd for C\(_9\)H\(_{12}\)NO\(_3\): C, 49.76; H, 6.91; N, 6.45. Found: C, 50.00; H, 7.14; N, 6.69. Ir (film): 1745, 1630, 1600. \(^{13}\)C Nmr: 170.6 (C=O), 155.0 (C-3), 102.9 (C\(_\alpha\)H), 79.1 (C-5), 58.0 (C-4), 54.9 (OMe), 53.5 (OMe), 52.6 (OMe), 12.5 (Me). Ms, m/z(%): 186 (5), 126 (16), 101 (3), 75 (100).

REFERENCES AND NOTES

14. Similar acid-catalyzed conversions of alkoxyfuranones into open-chain acetal-esters, with concomitant
Z-E (or cis-trans) isomerization, have been reported by us in 5-alkoxyfuran-2(5H)-ones3ab, and in their
Diels-Alder cycloadducts.21c
