Abstract- 2R,5S-dihydroxymethyl-3R,4R-dihydroxypyrrolidine (1) has been prepared from D-glucosamic acid which has four stereocenters in the same absolute stereochemistry as required for 1.

Many polyhydroxylated alkaloids are important sugar analogues in which the ring oxygen atom is replaced by the nitrogen functionality. These natural and synthetic polyhydroxylated aza sugar have displayed inhibitor of glucosidase and mannosidase.1,2 There is growing interest in synthetic methodologies towards polyhydroxylated pyrrolidine since 2R,5R-dihydroxymethyl-3R,4R-dihydroxypyrrolidine (2), isolated from Derris ellipica3 has been shown to be a potent inhibitor of viral glucoprotein processing glucosidase.4 Among compound (2) derivatives or epimers, 2R,5S-dihydroxymethyl-3R,4R-dihydroxypyrrolidine (1) which is C-5-epimer of 2, is a potent inhibitor of a number of glucosidase.5a This valuable compound (1) has been easily prepared from 1,4-butenediol or 5-keto-D-fructose via chemical and enzymatic procedures.5 These procedures have overcome the problem of diastereoselectivity, but still may has the disadvantage of being nonenantioselective.

Our objective is to develop a short and efficient route to prepare enantiomerically pure 1. As our chiral educt we choose glucosamic acid which has all four stereocenters in the same absolute stereochemistry as required for C-2, C-3, C-4 and C-5 in 1. The main feature of this method is selective hydrolysis of terminal isopropylidene group7 and intramolecular nucleophilic amination (Scheme 1).

The gluconate (3) was synthesized readily and in high yield from glucosamic acid as described6 and was treated under standard condition for introducing the benzylxoycarbonyl group, and the resulting ester (4), a stable and crystalline compound, was obtained in 74% yield from glucosamic acid. The diisopropylidene gluconate (4) was exposed to 110 w/w% of Dowex 50W-X8 resin (H+ form) in 90% methanol, and
terminal isopropylidene group was selectively hydrolyzed in excellent yield. This highly selectivity is believed to be due to bounded protons and steric effect of heterogeneous catalyst (Dowex-X8).7a

**Scheme 1**

The primary hydroxy group of 5 was selectively protected with t-butyldimethylsilyl chloride followed by mesylation of corresponding silylate 6 with mesyl chloride gave mesylate (7) in 89% yield from 5. Simply reduction of 6 with LiAlH₄ in THF gave alcohol (8) in 89% yield. The remaining isopropylidene and t-butyldimethylsilyl groups of 8 were easily removed by treatment of alcohol (8) with Dowex 50W-X8 in methanol. Subsequent hydrogenolysis of corresponding benzylcarbamate in the presence of palladium on charcoal and triethylamine removed the benzyloxy carbonyl group and led to direct nucleophilic amination to afford 1 in 62% yield from 8. Its physical and spectral properties correlated well with previous reported.5

**EXPERIMENTAL**

General. Dowex 50W-X8 was purchased from Sigma Chemical Co. All non-aqueous reaction were carried out under an inert nitrogen atmosphere. Tetrahydrofuran (THF) was distilled from
Na/benzophenone; acetonitrile, 2,2-dimethoxypropane, dimethylformamide (DMF), and methylene chloride were distilled from CaH₂. Column chromatography was carried out using 230-400 mesh silica gel. Mps were measured on Thomas-Hoover Capillary Apparatus and are uncorrected. Specific rotation values were measured on JASCO DIP-370 polarimeter. Proton and carbon nmr spectra were measured down field relative to tetramethyl silane in CDCl₃ unless otherwise noted (value in ppm); ¹H-nmr, ¹³C-nmr were conducted on 200-, 300-, or 400 MHz spectrometer. The elemental analysis was carried out by the Korea Research Institute of Chemical Technology. Final solutions before evaporation were dried over anhydrous Na₂SO₄.
