Abstract — New phosphorus-selenium heterocycles, dibenzophosphaselenocines (1 and 2), have been prepared. The structure of the dibenzophosphaselenocines was determined by multinuclear nmr spectroscopy and X-ray diffraction analysis.

There has been considerable interest in the transannular interaction or bond formation (e.g., dication formation) between heteroatoms in medium-sized heterocyclic compounds containing nitrogen and/or sulfur atoms. In contrast, such interactions and the properties of heterocycles involving selenium or two different heteroatoms are not well explored. This paper presents the first synthesis, property, and crystal structure of new dibenzophosphaselenocines (1 and 2). The conformational work of phosphorus-heterocycles has been conducted with rings containing O-P-O unit, since these are generally easier to synthesize. However, little is known about the property of phosphorus-heterocycles containing CH2-P-CH2 unit.

New phosphorus-selenium heterocycles (1) and (2) were synthesized as follows. Bis-bromide (7) (1.00 g, 2.16 mmol) in CH2Cl2 (500 ml)-EtOH (500 ml) was treated with Na2Se (297 mg, 2.38 mmol) in EtOH (10 ml) using a high dilution technique under an Ar atmosphere at room temperature. The whole mixture was stirred at room temperature for 24 h. After work-up, the crude products were purified by preparative liquid chromatography to give 12-phenyl-5H,7H-dibenzo[c, f][1,5]phosphaselenocine 12-oxide (1) (81%) (Scheme 1).
Solutions of bis(2-bromomethyl)phenyl selenide (8) (2.00 g, 4.77 mmol) in anhydrous THF (100 ml) and PhPLi₂ (4.77 mmol) in anhydrous THF (100 ml) were added separately and simultaneously over 60 min to a stirred solution of anhydrous THF (400 ml) under an Ar stream. The mixture was stirred at room temperature for 18 h, after which it was worked up. The crude products were purified by silica gel column chromatography (eluent, CHCl₃-MeOH) to afford 6-phenyl-5H,7H-dibenzo[b,g][1,5]phosphaselenocine 6-oxide (2) (2%) and 5,6-dihydrodibenzo[b,f]selenepn (3) (75%) (Scheme 2). The selenepin (3) could be produced by the radical coupling of the benzylic carbon radical (6) generated via an electron transfer pathway of the phosphonium anion toward the bis-bromide (8). The phosphine oxide (2) would be obtained during the work-up of the reaction mixture, since the phosphine (5) was formed on treatment of phosphine oxide (2) with PhSiH₃.

The conformers of 1 and 2 can be assigned by the ¹H-nmr spectral data for benzylic methylene protons of the eight-membered ring. The ¹H-nmr spectrum of 1 in CDCl₃ at 25 °C shows the benzylic protons as two types of AB quartet peaks at δ 3.60, 3.70 (J = 12.5 Hz) and 3.86, 4.11 (J = 12.7 Hz), which are assigned to a twist-boat form (1a) (vide infra).

When the phosphine oxide (1) was dissolved in concentrated D₂SO₄ (98%) at room temperature, the conformation of 1 in CDCl₃ was changed completely to the boat-boat form, dication (4) in D₂SO₄, as shown by ¹H-nmr spectroscopy, i.e., the benzylic methylene protons appear at δ 4.91, 5.13 (ABq, J = 15.5 Hz). The ⁷⁷Se-chemical shift of 4 in D₂SO₄ is δ 387.8. While, the ³¹P-nmr spectrum of 4 in
D₂SO₄ shows a remarkable downfield shift to δ 104.9 from δ 26.0 for 1 in CDCl₃. More significant spectroscopic evidence for the formation of 4 was obtained in the both ³¹P and ⁷⁷Se-nmr spectra; the proton-decoupled ³¹P and ⁷⁷Se-nmr spectra of 4 exhibit the ³¹P-⁷⁷Se coupling (JₚSe = 252 Hz). This observation indicates the occurrence of transannular bond formation between phosphorus and selenium atoms. The phosphine oxide (1) was recovered quantitatively after hydrolysis of 4.

Interestingly, treatment of 1 with PhSiH₃ (3 equiv) in toluene under reflux gave the phosphane-selenide (9) (17%) (Scheme 1). The X-ray analysis of 9 reveals the twist-boat form (9a) (Figure 1). Meanwhile, the donor-acceptor complex (10) of the phosphine oxide 2 and SbCl₅ shows the boat-chair form as evidenced from the X-ray crystal data (Figure 2).
