Abstract - The tryptophan pseudodipeptides (8) and (13) were synthesized via generation of the tryptophan backbone through the reaction of a succinylaminomalonate with a quaternarized gramine.

The amazing inhibition of matrix metalloproteinases by simple long chain fatty acids¹ asks the question of their site(s) of interaction with the enzymes, as compared with those of the known biologically active hydroxamate derivatives of N-succinyltryptophanamides.² To this purpose, it was of interest to develop a versatile synthesis of N-succinyltryptophanamides (1) that might allow introduction of various lipophilic substituents (Scheme 1).

While tryptophan dipeptides are most generally synthesized through classical peptide chemistry, application of the chemistry of gramines³ seemed not to have been used to this purpose. As racemates were suitable for preliminary biological investigations, we then engaged ourselves in the construction of racemic compounds by reacting a quaternarized gramine with a suitably acylated aminomalonate. In particular, this approach makes it possible to introduce a dialkylaminoethyl R² substituent⁴ and it should further open the way to combinatorial syntheses. The straightforward synthesis of model compounds (1) (R¹ = n-Hex, R² = H or (CH₂)₂NMe₂, R³ = H) along such lines was performed in this preliminary work.
RESULTS

The protected diethyl succinylaminomalonate (2) (Scheme 2) obtained from tert-butyl succinate\(^5\) was hydrolyzed (TFA) to the acid (3), which was reacted with \(O\)-benzylhydroxylamine (DCC, HOBr) to yield the protected hydroxamic acid (4). Reaction of 4 with gramine methiodide smoothly gave the diester (5), which was saponified and decarboxylated to the tryptophan derivative (6). Amidation of 6 with \(n\)-hexylamine (DCC) and further hydrogenolysis finally gave the hydroxamic acid (8).

Reagents : (i) \(\text{H}_2\text{NCH(CO}_2\text{Et)}_2\), DCC, \(\text{CH}_2\text{Cl}_2\), rt, 16 h, 92%; (ii) TFA, \(\text{CH}_2\text{Cl}_2\), rt, 24 h, 93%; (iii) \(\text{BnOH}_2\text{HCl, Et}_3\text{N, HOBr, DCC, CH}_2\text{Cl}_2\), rt, 16 h, 73%; (iv) a) \(\text{NaH, THF, } 0\text{\degree C, } 15\text{ min, b) gramine methiodide, reflux, 16 h, 63%}; (v) a) \(\text{NaOH, MeOH/H}_2\text{O 5:2, rt, 64 h, b) HCl, evaporation of MeOH, reflux, 3 h, 79%}; (vi) \(n\)-HexNH\(_2\), DCC, \(\text{CH}_2\text{Cl}_2/\text{DMF, rt, 15 h, 50%}}; (vii) \(\text{H}_2/10\% \text{Pd/C, EtOH, rt, 2 h, 96\%}.

Scheme 2

The \(^1\text{H}\) and \(^{13}\text{C}\) NMR spectra and the MS spectra of the compounds were consistent with the structures. In particular, the MS spectra of compounds (5-7) exhibited a peak at \(M^+ - 106\) due to the loss of PhCHO along a McLafferty's rearrangement; the hydroxamic acid (8) gave a characteristic violet spot on TLC after spraying with a \(\text{FeCl}_3\) solution.\(^6\)

Then, although the yields and the length of the synthesis compare disfavorably with those of a direct synthesis of 7 from a tryptophanamide, obtaining 8 nevertheless illustrates the feasibility of such an alternative way.

Application to the synthesis of 13 along similar lines (Scheme 3) further demonstrates the usefulness of the process. Thus, tetrahydro-\(\gamma\)-carboline methiodide (9) reacted with the amidomalonate (4) to yield the 2-substituted tryptophan derivative (10). Attempts to saponify and decarboxylate 10 as performed with 5 failed, and replacement of \(\text{NaOH with LiOH, followed by acidic treatment unexpectedly gave ester (11)}, indicating that the saponification had affected only one ester group in 10.\(^7\) Ester (11) was transformed into
amide (12) in the presence of AlMe₃, and further submitted to hydrogenolysis to yield the hydroxamic acid (13). The structures of compounds (10-13) were ascertained by their spectroscopic data.

EXPERIMENTAL

Commercially available reagents purchased from Acros Organics were used without further purification. Melting points were measured with a Reichert microscope apparatus and were uncorrected. UV spectra (nm) were recorded on an UNICAM 8700 apparatus, IR spectra (cm⁻¹) on a BOMEM MB series spectrophotometer. ¹H (300 MHz) and ¹³C NMR (75 MHz) spectra were measured on a Bruker AC 300 instrument with TMS as internal reference. MS spectra were determined on a VG Autospec apparatus. Elemental analyses were carried out by the microanalyses service of the Faculty of Sciences, University of Reims Champagne Ardenne. Preparative column chromatography was performed on Kieselgel 60 silica gel; for TLC control Kieselgel-60 PF254 plates were used.

Diethyl 2-[[4-(tert-butoxy)-4-oxobutanooyl]amino]malonate (2). A solution of DCC (5.73 g, 27 mmol) in 30 mL of CH₂Cl₂ was added to a solution of diethyl aminomalonate (4.8 g, 27 mmol) and tert-butyl succinate (4.76 g, 27 mmol) in 70 mL of CH₂Cl₂. The residue was chromatographed on silica gel (CH₂Cl₂/0-2% MeOH) to yield 2 as an oil (8.31 g, 92%).

**N'1-(benzyloxy)-N'4-[2-[dimethylaminoethyl]-1H-indol-3-yl]-1-(hexylcarbamoyl)ethyl]succinamide (12).** A solution of n-hexylamine (100 mL, 0.75 mmol) in CH2Cl2 (2 mL) was cooled to 0°C and 2 M trimethylaluminium in hexane (0.4 mL, 0.8 mmol) was added under nitrogen. The mixture was stirred at 0°C for 30 min and was added via a syringe to a suspension of 11 (118 mg, 0.23 mmol) in CH2Cl2 (2 mL). The reaction mixture was allowed to warm up to rt and stirred for 40 h. Then H2O was added and the mixture was extracted three times with CH2Cl2.
