Diphenyl-3,8-methanothionin (1), the first example of bridged ten-π-electron [9]annulene, could be isolated by thermal fragmentation of the cycloadduct (2a), which was formed by the reaction between benzcyclopropene and a mesoionic dithiolen (3). Photolysis of the adduct (2), on the other hand, gave a cyclohept[a]thiophene (4), an isomer of the methanothionin.

Peracid oxidation of the adduct (2a) gave the corresponding S-oxide (2b). Although pyrolysis of the S-oxide resulted in a complex mixture, photolysis of the S-oxide gave two isomers of cyclohept[a]thiopyransones (5a and 5b) as the main products, and a fraction which may be considered as consisting of a 4,7-methanothiecinone (6) and an isomer of the S-oxide.
