NITRILES IN HETEROCYCLIC SYNTHESIS: A NEW APPROACH FOR THE
SYNTHESIS OF THIAZINONES

Abstract - Synthesis of thiazines via the reaction of thiosalicylic acid with malononitrile, ethyl cyanoacetate and other polyfunctional nitriles is reported.

Polyfunctional nitriles are highly reactive compounds that have been extensively utilized in organic synthesis.\(^1,2\) In the last decade, we have been involved in a program aiming to explore the potential scope and limitation of the utility of polyfunctional nitriles in heterocyclic synthesis.\(^3\) During this phase of our research, we have developed a new synthesis of 2-thiazolin-4-ones from reaction of cyanocarbonic acid derivatives with thioglycolic acid.\(^4-7\) We have been particularly interested to see if the reaction of polyfunctional nitriles with bidentate thioles reagents can be utilized as a general approach for synthesis of sulphur containing heterocycles.

In the present paper, we report the result of our investigation on the reaction of thiosalicylic acid (1) with cyanocarbonic acid derivatives. Thus it has been found that when equimolecular amounts of malononitrile (0.01 mole) and 1 (0.01 mole) were refluxed in acetic acid (50 ml) for 2 h, a mixture of two products of melting points 220°C and 310°C in the ratio of 3:1 respectively was obtained. These were separated by fractional crystallization from ethanol. The product of mp 220°C revealed a molecular formula of \(\text{C}_{10}\text{H}_{6}\text{N}_{2}\text{O}_{5}\). The thiazine structure 2a was assigned for this product based on IR and \(^1\)H NMR data. Thus, the \(^1\)H NMR in trifluoroacetic acid (TFA) revealed low field aromatic proton at \(\delta\) 8.22 for H-5 proton, a multiplet for three protons extending from \(\delta\) 7.25 - 7.9 ppm for H-6, H-7 and H-8. The methylene protons appeared as multiplet at \(\delta\) 4.69 - 5 ppm indicating that this molecule exists in TFA as a mixture for 2a and its protonated forms 4-6. A signal for 0.50 H appeared at \(\delta\) 6.66 ppm for the protonated form. However, it is difficult to decide if protonation afforded, 4, 5 or 6, most likely the three forms exist.
In order to shed further light on the actual structure of this reaction product, its pKa was determined spectrophotometrically and a value of 8.5 was observed. This indicates that the molecule is more acidic than phenolate anion. This extra acidity may be rationalized by assuming that the conjugate base of this molecule is stabilized by the resonance of negative charge on the oxygen, nitrogen, ring carbons and the exocyclic CH-CN moiety (cf. structure 7). The product which exhibit high melting point could be formed on treatment of 2a with another molecule of 1 and was assigned structure 8 based on its analytical data. Compound 2a could be obtained as the sole reaction product on treatment of
1 with malononitrile in refluxing pyridine. However, under acidic conditions
compound 8 was always obtained as a byproduct with 2a. It seems that the reaction
of 2a with 1 in acidic medium proceeds at an appreciable rate so that this
reaction competes successfully leading to the formation of 8. However the possi-
bility, that 1 reacts with malononitrile to yield acyclic intermediate 3 which
then either loose a water molecule to yield 2a or reacts further with 1 to yield
9 which affords final isolable 8, cannot be overlooked.
Similar to the behaviour of 1 toward malononitrile, it reacted with cyanoacet-
amide and cyanoacetanilide in refluxing pyridine to yield the corresponding
thiazines 2b,c.
In contrast to the observed reaction of 1 with malononitrile and cyanoacetamides,
ethyl cyanoacetate (0.01 mole reacted with 1 (0.01 mole) when refluxed in
ethanol (50 ml) in presence of 0.1 ml of triethylamine for 4 h yielding a
product of molecular formula C₁₇H₁₁N₂O₄S₂. Attempts to effect this reaction in
acetic acid were unsuccessful. Structure 10 was suggested for the product based
on spectral data. Thus, ¹H NMR of the reaction product indicated that the comp-
ound exists mainly in the tautomer shown in formula as it revealed absence of
any absorption for protons linked to sp³ carbons.
When 1 was treated with ethyl cyanoacetate in refluxing pyridine for 3 h,
compound 2d was formed. Attempts to convert 2d into 10 on treatment with 1
(route b) in ethanolic triethylamine were unsuccessful. The thiazine derivative
2d was recovered unchanged indicating that 10 was formed via route a.
Cyanothioacetamide (0.01 mole) reacted with 1 (0.01 mole) in refluxing pyridine
(30 ml) for 3 h to yield the bithiazine derivative 12. This is assumed to be
formed via self condensation of intermediate thiazine to yield the isolable
product. Similar condensation of active methylene reagents with thioamides are
well known.¹⁰
Trichloroacetonitrile (0.01 mole) was refluxed with 1 (0.01 mole) in dry toluene
(30 ml) for 3 h to yield a product of molecular formula C₁₆H₈N₂O₂S₂Cl₃. This was
assigned structure 13 based on analytical and spectral data. Similar observation
has been very recently reported by one of us¹¹ for the reaction of methyl
salicylate with trichloroacetonitrile.
All the reported products were formed in good yields. The chemistry of these
compounds is now under investigation.
