**Abstract** — Berberis actinacantha Mart. ex Schult. (Berberidaceae) has yielded the new proaporphine-benzylisoquinolines (+)-epiberbivaldine (13) and (+)-rupancamine (15). The first of these dimers belongs to the epi stereochemical series, while the second incorporates the normal stereochemistry at C-13.

Proaporphine-benzylisoquinoline dimers have been found only among the Berberidaceae.<sup>1</sup> They originate biogenetically from intramolecular oxidative coupling of the bisbenzylisoquinoline (+)-berbamunine (1) or one of its close relatives.<sup>2</sup> Proaporphine-benzylisoquinolines may be subdivided into two classes. The more common and hitherto the more prevalent class is represented by the alkaloid (+)-pakistanamine (2) and its analogs (+)-valdiberine (3), (+)-berbivaldine (4), (+)-valdivianine (5) and (+)-patagonine (6) which incorporate the "normal" stereochemistry at the spiro C-13 center. When treated with acid, these alkaloids rearranged to aporphine-benzylisoquinoline dimers 7-11, respectively, substituted at C-1,2,9,10 on the aporphine moiety.<sup>2,3</sup>

The less common variety of proaporphine-benzylisoquinolines included, up to the present study, only (+)-epivaldiberine (12) which rearranged to an analog of the C-1,2,10,11-substituted aporphine-benzylisoquinoline 14. Valdiberine and epivaldiberine were both found in Berberis valdiviana. But whereas 15 mg of (+)-valdiberine (3) were obtained from 10 kg of the plant, only 1 mg of the diastereomeric (+)-epivaldiberine (12) could be found.<sup>3</sup> Although never specifically so stated, one was thus left with the lingering impression that proaporphine-benzylisoquinolines of the normal series were more common and prevalent than those of the epi series.

The stereochemistry at C-13 of (+)-pakistanamine (2) and its analogs of the normal series was originally determined by a detailed NMR NOEDS study on 2. But the stereochemistry of (+)-epivaldiberine (12) was deduced indirectly mainly through its rearrangement product (analog of 14),

since insufficient amounts were available for NOEDS.<sup>3</sup> Presently, we have found that *B. actinacantha* Mart. ex Schult. (7.28 kg) produces an array of proaporphine-benzylisoquinolines including (+)-pakistanamine (2) (5 mg), (+)-berbivaldine (4) (4 mg) and (+)-patagonine (6) (60 mg).<sup>4</sup> The most significant product found, however, was the new amorphous dimer (+)-epiberbivaldine (13), C<sub>36</sub>H<sub>38</sub>N<sub>2</sub>O<sub>6</sub>,  $\nu$  max CHCl<sub>3</sub> 1645, 1675, 3555 cm<sup>-1</sup>, diastereomeric with (+)-berbivaldine (4), and obtained in the relatively generous amount of 45 mg. The 360 MHz CDCl<sub>3</sub> NMR spectrum has been summarized around expression 13. The ring D vinylic doublet at  $\delta$  6.36 is diagnostic of the epi series, and so is the well defined A<sub>2</sub>B<sub>2</sub> system at  $\delta$  6.89 d and 6.99 d due to the protons of ring C'.<sup>3</sup> Since, for the first time, we had on hand a dimer of the epi series in sufficient amounts, the alkaloid was subjected to an NMR NOEDS analysis<sup>5</sup> to confirm independently the stereochemistry at C-13.<sup>6</sup> The results are presented around expression 13-NOE. A telling feature is the 13.8% NOE of H-12 ( $\delta$  6.36) upon irradiation of H-6a ( $\delta$  3.34), so that these hydrogens must be proximate. The mass spectrum of (+)-epiberbivaldine (13) includes molecular ion  $m/z$  594 (19), and base ion  $m/z$  192 representing rings A' and B' of the tetrahydrobenzylisoquinoline moiety.<sup>7</sup> Final proof of structure was supplied by the acid catalyzed rearrangement of (+)-epiberbivaldine (13) to the amorphous (-)-aporphine-benzylisoquinoline 14, C<sub>36</sub>H<sub>38</sub>N<sub>2</sub>O<sub>6</sub>.<sup>8</sup> The 200 MHz NMR CDCl<sub>3</sub> spectrum is quoted around expression 14. Significantly, the downfield aromatic absorption near  $\delta$  8.1 due to H-11 of an aporphine is missing since that site is substituted. Another new proaporphine-benzylisoquinoline dimer we subsequently obtained from the same source is the amorphous and monophenolic (+)-rupancamine (15), C<sub>37</sub>H<sub>40</sub>N<sub>2</sub>O<sub>6</sub>,  $\nu$  max CHCl<sub>3</sub> 1645, 1670, 3550 cm<sup>-1</sup>.<sup>9</sup> This normal alkaloid was present in lesser amount (23 mg) than epiberbivaldine (13) (45 mg). In the 200 MHz CDCl<sub>3</sub> spectrum (expression 15), the ring D vinylic doublet is relatively upfield at  $\delta$  5.92, in accord with the normal stereochemistry.<sup>3</sup> Furthermore, the A<sub>2</sub>B<sub>2</sub> system representing the ring C' protons falls between  $\delta$  6.94 and 7.00, and is less well delineated than in epiberbivaldine. The mass spectrum shows molecular ion  $m/z$  608 (6), and base peak  $m/z$  192.<sup>9</sup> To complete the structure elucidation, rupancamine was rearranged to amorphous aporphine-benzylisoquinoline (+)-16, C<sub>37</sub>H<sub>40</sub>N<sub>2</sub>O<sub>6</sub>, whose NMR spectrum (200 MHz, CDCl<sub>3</sub>) included a singlet at  $\delta$  8.10 representing H-11.<sup>10</sup> The isolation of relatively large amounts of epiberbivaldine, accompanied by other proaporphine-benzylisoquinolines of the alternate normal stereochemistry, indicates that both series may exist in a plant in abundance. The amounts present probably depend upon the different enzymes responsible for the intramolecular oxidative coupling of the bisbenzylisoquinoline precursor(s).
