Abstract – An efficient and environmentally benign method was developed for the facile synthesis of various 2-aryl and 2-alkyl substituted benzothiazoles in moderate to good yields, using a silver-mediated redox condensation of benzothiazoles and aldehydes in water. Furthermore, this method is also applicable to prepare 2-acyl benzothiazoles.

INTRODUCTION

2-Substituted benzothiazoles are important building blocks of pharmaceuticals and natural products. For instance, the antitumor and anti-hepatitis C virus (anti-HCV) drug molecules contain benzothiazole moieties (Scheme 1). Therefore, the development of efficient methods for the synthesis of 2-substituted benzothiazoles and its analogues has drawn much attention.

Scheme 1. Some Drugs Contain 2-Substituted Benzothiazole
To date, some synthetic routes have been developed for the preparation of 2-substituted benzothiazoles. It can be divided into three broad categories: (1) the condensation of 2-aminothiophenols with aryl aldehydes, carboxylic acids, nitriles, acyl chlorides, or alcohols;3 (2) transition metal-catalyzed direct C–H activation and C–C coupling of benzothiazole with aryl halides, arylboronic acids, iodo benzenediacetate, arenediazonium salts, aryl sulfamates, aryltrimethylammonium triflates, arylenebenzenesulfonyl chlorides, substituted benzoic acids, or triarylbumuth reagents;4 (3) redox condensation of benzothiazoles with aldehydes, benzylic alcohols, and styrenes.5 However, there are some drawbacks in the above methods. For example, the expensive and unstable 2-aminothiophenol was used as starting materials; expensive transition metal was used as catalysts. To continue our interest in silver catalysis,6 we report herein a silver-mediated redox condensation of benzothiazoles with aromatic and aliphatic aldehydes, as well as phenylglyoxal in water, affording a variety of 2-aryl, 2-alkyl, and 2-acyl substituted benzothiazoles in high yields.

RESULTS AND DISCUSSION

Initially, the redox condensation of benzothiazole (1a) and benzaldehyde (2a) in AcOH-H2O (8:2) at 100 °C for 24 h under air was chosen as a model reaction. As shown in Table 1, the different oxidants such as AgOTf, AgNO3, Ag2CO3, AgOTs, DTBP, Cu(OAc)2, and O2 were investigated (entries 1–7). And the highest yield of 3a (88%) was obtained using AgOTs as an oxidant. However, the yield of 3a was decreased with the decrease of the amount of oxidant (entries 8–9). Interestingly, up to 90% yield was obtained when the reaction was performed under nitrogen atmosphere (entry 10). It maybe ascribe to the oxidation of the benzaldehyde to benzoic acid under air.7 It was found that there is no effect on the yield even if shortening the reaction time to 12 h (entries 10–12). Next, the ratio of AcOH and H2O was examined (entries 13–15). An 81% yield of 3a was obtained in an equal volume of AcOH and H2O (entry 13). To our delight, 3a was isolated with 95% yield in H2O (entry 15). And then, the reaction was also conducted at lower temperature, but the yield decreased apparently (entries 16–17). The structure of 3a was determined not only by 1H NMR, 13C NMR, and HRMS, but also by single crystal X-ray analysis (CCDC 1814089).

With the optimized reaction conditions in hand, the substrate scope was investigated. As shown in Scheme 2, the reaction of benzothiazole (1a) with both electron-poor and electron-rich aromatic aldehydes was conducted smoothly, giving the corresponding products 3b–3n in 46–95% yield. Notably, the aldehydes bearing a free hydroxyl group or methylal moiety were also tolerated, providing the desired products 3m and 3n in 46% and 63% yields, respectively. In addition, the 1-naphthaldehyde (2o) and furan-2-carbaldehyde (2p) were also applicable to this reaction, and the desired benzothiazoles 3o and 3p were obtained in 87% and 79% yields, respectively. To our delighted, the aliphatic aldehydes like
cyclohexanecarbaldehyde (2q), cyclopentanecarbaldehyde (2r), cyclopropanecarbaldehyde (2s), isobutyraldehyde (2t), 2-methylbutanal (2u), as well as 2-phenylpropanal (2v) are also applicable, and the corresponding products 3q–3v were obtained in 64–85% yield. Subsequently, the scope of benzothiazoles was also examined. For example, the electron-poor 6-bromobenzothiazole and electron-rich 6-methoxybenzothiazole gave the desired product 3w and 3x in 85% and 69% yields, respectively.

Aryl heteroaryl ketones are important skeletons of pharmaceuticals, such as diflumidone, raloxifene and tiaprofenic acid. Liu and Wang reported the redox condensation of benzothiazoles with phenylglyoxal, and 2-benzoylbenzothiazole was obtained with only 31% and 44% yields. To further demonstrate the scope of this methodology, the phenylglyoxal 4a and methylglyoxal 4b were also subjected to the

reaction with benzothiazoles (Scheme 3). To our delighted, the corresponding 2-benzoylbenzothiazoles 5a–5c and 2-acetylbenzothiazole 5d were obtained in 69–90% yields.

To understand the reaction pathway, several control experiments were performed. As shown in Scheme 4, under the standard conditions, the benzaldehyde remained intact (eq. 1), whereas benzothiazole was completely consumed to give 2-aminothiophenol quantitatively (eq. 2). The reaction of benzaldehyde and 2-amino thiophenol proceeded smoothly to give the desired product in 95% yield (eq. 3).

Scheme 4. Control Experiments. Standard conditions: AgOTs (2 equiv), H2O (2 mL), 12 h, 100 °C, under N2 atmosphere.

Based on the results of control experiments and previous reports, a possible reaction pathway was proposed as shown in Scheme 5. Initially, the benzothiazole (1a) will be opened to give 2-aminobenzenethiol I by silver salt. And then, the condensation of intermediate I with benzaldehyde (2a) will generate imine II. Next, the intramolecular cyclization of imine II will produce III, followed by oxidation to give the desired product 3a.

Scheme 5. A Possible Reaction Pathway

In summary, we have developed an efficient method for the synthesis of 2-aryl, 2-alkyl, and 2-acyl-benzothiazoles from readily available benzothiazoles and corresponding aldehydes in the presence of silver salt with water as green solvent. Further studies on the detail mechanism and the scope of other heteroaromatics like benzoimidazoles, benzoxazoles are underway in our laboratory.

**General procedure for the synthesis of products**

A sealed pressure vessel was charged with benzothiazole (68 mg, 0.5 mmol), AgOTs (280 mg, 1 mmol), aldehyde (0.6 mmol) and 2.0 mL of H₂O.
