Abstract - The reaction of 3-substituted 2-(*N*-cyanoimino)thiazolidine (NCT) derivatives with hydrazine hydrate afforded two types of 1,2,4-triazoles *via* a selective C₂-S or C₂-N₃ bond fission, in which the selectivity was controlled by the N₃-substituent.

2-(*N*-Cyanoimino)thiazolidine (NCT)(1)¹ has various functionalities in its small molecule, and therefore it is expected to exhibit diverse reactivities and to be a useful synthon for many heterocycles. In the previous papers, we have reported the synthesis of imidazo[2,1-*b*]thiazole and thiazolo[3,2-*b*]-1,2,4-triazole derivatives by the cyclization of the compounds bearing active methylene group at N₃ (2) and through the N₃-amination of 1, respectively, and also reported a selective cleavage of N₃-CO bond of 3-acyl-NCT (3) by amines, alcohols, and thiols to afford amides, esters, and thioesters, respectively.² As one of the continuous studies on reactivity of NCT derivatives, we now report a novel synthetic route to 1,2,4-triazoles by the reaction of compound (1) and 3-substituted NCTs (4³ and 5²) with hydrazine hydrate *via* the N₃-substituent-directed bond fission at C₂-S or C₂-N₃ (Scheme 1).

* Satisfactory microanalyses were obtained for all compounds.

Treatment of 3-methanesulfonyl-NCT (**4**: R=Me) with 3 equivalents of hydrazine hydrate in boiling ethanol gave the 1,2,4-triazole (**6**: R=Me) in 61% yield. Other 3-arylsulfonyl-NCTs (**4**: R=*p*-MeC₆H₄, *p*-ClC₆H₄) also gave the similar results. On the other hand, the reaction of the nonsubstituted NCT (**1**) with hydrazine hydrate under the same conditions produced another type of 1,2,4-triazole (**7**: Y=H) exclusively in 90% yield. The same type of 1,2,4-triazoles (**7**) was also obtained in the case of 3-alkyl-NCTs (**5**). The results are summarized in Table. Since more rapid formation of the disulfides (**7**) is observed in an oxygen atmosphere than in air, compound (**7**) is assumed to be generated by the air oxidation of the initially formed thiol (**8**). Compound (**7**) was treated with zinc in a mixture of acetic acid and acetic anhydride to afford a triacetate (**9**; Y=Ac: when Y=H in **7**) or a diacetate (**9**; Y=alkyl)⁴(Scheme 2).

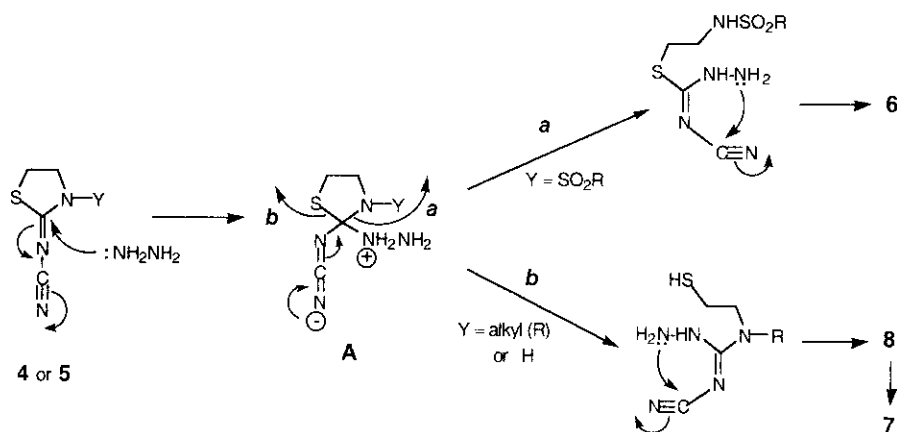

Scheme 2

In these reactions, the addition of hydrazine at C₂ would afford a carbodiimide intermediate (**A**). When the carbodiimide part returns to a cyanoimine, a bond fission (**a** or **b**) would occur. Namely, in the 3-arylsulfonyl derivatives (**4**), the C₂-N₃ bond fission (**a**) followed by the intramolecular cyclization between the nitrile group and the hydrazine moiety gives the triazole (**6**). Contrary to the sulfonylated derivatives, the C₂-S bond cleavage (**b**) takes place in nonsubstituted or 3-alkyl-NCT (**1** or **5**), and subsequent intramolecular cyclization produces a triazole thiol (**8**), which is readily oxidized in the air to afford the disulfide (**7**)(Scheme 3).

The fission **a** would afford a nitrogen anion and the fission **b** afford a thio anion. When Y is a sulfonyl group, the former is more stable than the latter. On the other hand, when Y is a hydrogen or an alkyl, the latter is more stable. Accordingly, the N₃-substituent controlled the direction of the bond cleavage and different type 1,2,4-triazoles were obtained.

As NCT is obtainable by one-step from the commercially available starting materials and various alkyl or sulfonyl group can easily be introduced at N₃, new facile synthetic route to two types of 1,2,4-triazoles were developed by changing the substituent of N₃.⁵
